

## **CIS 545 - Big Data Analytics**

### **Project Proposal**

#### **1) Group Members:**

- 1) Arvind Balaji Narayan  
Pennkey: narvind  
Penn Mail: [narvind@seas.upenn.edu](mailto:narvind@seas.upenn.edu)  
Responsibilities: [Data Cleaning, EDA (Exploratory Data Analysis) & Predictive Modeling]
  - 2) Bharathrushab Manthripragada  
Pennkey: mbharath  
Penn Mail: [mbharath@seas.upenn.edu](mailto:mbharath@seas.upenn.edu)  
Responsibilities: [Data Cleaning, EDA (Exploratory Data Analysis) & Predictive Modeling]
  - 3) Gopik Anand  
Pennkey: ganand  
Penn Mail: [ganand@seas.upenn.edu](mailto:ganand@seas.upenn.edu)  
Responsibilities: [Data Cleaning, EDA (Exploratory Data Analysis) & Predictive Modeling]
- 

#### **2) Data Source:**

We will be using the **arXiv Dataset** from Kaggle specified as part of the Course Staff Proposed Datasets that can be used for the project.

Dataset Link: <https://www.kaggle.com/Cornell-University/arxiv>

---

#### **3) Project Plan**

##### **A) Intentions and Ultimate Objectives**

- 1) Perform an extensive study on the dataset at hand with attention to Abstracts and the broad domain of science to which the publication belongs.
- 2) Understand the data better using powerful visualization tools like Word Clouds, heat maps, etc.
- 3) Extract text pertaining to the Abstract and the corresponding domain/category to which the publication belongs in the right form and model the relationship between the two using various kinds of NLP techniques best suited for classification.

- 4) The ultimate objective, given the abstract of any published paper, is to predict the most (top 3 or top 5) relevant categories/domains to which the abstract of the paper would belong.

## B) Models Considering

- We will be using the standard NLP models such as TextCNN, BERT, LSTM, BiLSTM, RoBERTa, GPT-2, etc. for the task of abstract classification into the most relevant categories/ domains. We will also start with simpler models like Naive Bayes and SVM and move further to complex model architectures.
- 

## 4) Points of Interest

- 1) The dataset consists of Abstracts from various publications. Being able to predict the most relevant categories of a random publication from the abstract might be a daunting task to an individual if he does not have an idea of that particular domain. In this case, our model will be able to identify the most relevant categories to which the abstract belongs thereby helping the individual.
  - 2) Our implementation will come in very handy for students involved in research work or project work. Say, for example, they are starting their research process on a project in Data Science and have a reference paper at hand. They could pass in the abstract to our model and our model will predict the most relevant categories to which the paper pertains. Using the categories predicted, they can filter out their searches and obtain research publications that are closely related to their reference paper. This largely simplifies the paper scouting process and helps students to find relevant papers on which they start and proceed with their research from.
- 

## 5) Possible Challenges

- a) The arXiv dataset is huge and using transformer models like RoBERTa and the other variants would need significant GPU compute requirements. Doing this work in Google Colab does not guarantee big compute requirements and hence the session may just crash. Identifying the right compute requirements and working accordingly is one possible challenge.
  - b) Cleaning the data and extracting the information in the right format might be another possible challenge. The use of powerful visualization tools for EDA could be a challenge for the given text data.
- 

## 6) TA Name - Adithya Rathi

---
